

Master's Comprehensive Exam

Note any reservations that a practitioner ought to keep in mind when interpreting the results of (a).

- c. Calculate a 95% confidence interval for ratio of odds of a rating of "Tasty" from dining hall B relative to that of dining hall C.
- d. Administrators know that the cost per meal at dining halls A, B, and C, is \$7.20, \$8.10, and \$6.10, respectively. Describe a statistical technique that might be applied to test the null hypothesis that spending is unrelated to frequency of positive rating, vs. the alternative that increased spending is associated with a greater frequency of positive ratings.
- e. Now drop the assumption introduced in part (a), and assume instead that the raters choose to review the dining hall closest to them. Suppose further that dining hall C is adjacent to a cooking school, and the 45 raters who evaluated C were faculty of the cooking school. How does this affect your interpretation of part (a)?
